Schematic. The number of four grounding rods at the center of ten or more are preset. But the number of rods surrounding these central four may have to be increased to counterbalance whatever impoverished magnetic field may exist in your area! Clarence had to use a minimum of 56, but wished he had added at least ten to twenty more due to depletion of Earth Capture during rains.

Each ground rod is 8 feet long. Best if made of steel and clad with copper.

Each toroid is wound exactly the same. But before connecting them together, the right toroid is rotated one-half turn around and then both are laid down on your work bench. Connect the same leads lying underneath with each other, primary to primary and secondary to secondary, and then connect the same leads lying on top - facing up towards the ceiling - with each other.
